Online Resource 3

a) Graphs showing mean and median tissue pliability for normal skin and striae distensae (SD). In SD, mean and median pliability showed a decreasing trend. In normal skin, mean pliability increased over time with a reduction at week 6. Median pliability in normal skin showed no overall trend but reduced at week 3

b) The first graph shows adjusted mean differences for tissue pliability between normal and SD skin and the second graph displays adjusted means of tissue pliability in SD. The magnitude and direction of changes between time points for tissue tonometry in SD were similar between placebo and silicone gel
