Fig 1: Magnetic resonance imaging showing knee joint and synovial metastasis. In STIR PD sequences; sagittal plane images, there is a lesion that places in femur medial condyle epiphysae-metaphysaeal line which has a peripheral hyperintense signal and makes edematous changes in near bone. In the same sequences there is an increasement of synovial fluid in suprapatellar pouch and this location there is an another poor hyperintense lesion (bone and synovial metastase).
