Reviewer: Mr Fadel Derry

Level of interest: A paper whose findings are important to those with closely related research interests

Advice on publication: Unable to decide on acceptance or rejection until the authors have responded to the compulsory revisions

This is a well written case report with a valuable message. However I think that the authors are describing a typical case of Fournier's Gangrene of the scrotum. The positive culture of mixed culture of anaerobes with a gram positive aerobe is a typical finding associated with Fournier's Gangrene of the scrotum. The growth of MRSA in the culture results cannot be taken as evidence to a direct single causation link as claimed by the authors. I feel that the authors should consider revising their article.
