Reviewer's report:

Rare gallbladder adenomyomatosis presenting as atypical cholecystitis: A case report

Adenomyomatosis of gallbladder is a common condition reported in up to 5% of cholecystectomy specimens. This clinical entity frequently is an asymptomatic incidental finding (or may present with occasional abdominal pain), has no intrinsic malignant potential and usually requires no specific therapy. The primary clinical significance of this condition is due to similarities at imaging with gallbladder cancer.

The authors Sheng –Hong Lin report a patient of adenomyomatosis of gallbladder with fever alone and no abdominal pain. Even as several already known aspects of adenomyomatosis such as the classical findings on T2 weighted MRI images and Gallium 67 scan have been well described, on the basis of association of fever alone, case report cannot be recommended for publication especially when the haematological, biochemical and histological parameters are indicative of an acute inflammatory pathology.

Also the manuscript is full of typographic / grammatical errors.

Level of interest: An article of insufficient interest to warrant publication in a scientific/medical journal

Quality of written English: Not suitable for publication unless extensively edited

Statistical review: No, the manuscript does not need to be seen by a statistician.
