Reviewer's report

Title: Severe symptomatic hyponatremia during citalopram therapy

Version: 2 Date: 21 October 2003

Reviewer: James A Bourgeois

Reviewer's report:

This is a straightforward case report of a underecognized problem with the use of SSRI agents. It is not stated in the report if/when citalopram was discontinued and the connection with such discontinuation and resolution of SIADH. In addition, possible other sources of hyponatremia are not specified. The English suffers from awkward syntax and grammar and could benefit from editorial review on this issue. Literature search is limited as there are only 6 references, which are not called out in the text. Abstract is excessively long for a case report and redundantly repeated in the Background Section. Dose of fenitoin not specified (I assume this is phenytoin) and whether it was continued after discharge not mentioned either.

Quality of written English: Needs some language corrections before being published
