Comments to Authors

This is an interesting case report with some very good pictures. There are a few points to improve it.

1. The patient’s vision was hand movements with the presence of a relative afferent papillary defect and this suggests that there was already considerable damage that had occurred from the presence of this nematode.

2. From blood investigations it would be good to know whether there was an abnormally high eosinophil count leading to the thought that there was parasitic infection.

3. No information is given as to why the patient was given Prednisone. I am sure it was to reduce the amount of inflammation and the worm dying but I think it would be helpful to put this in. Also it is a problem giving people Prednisone without excluding TB and this needs to be addressed that this is what was done.
