The authors described improvement of visual acuity after trabeculotomy in a patient with neuromyelitis optica (NMO). I think that this is a valuable case report.

1. The clinical course of the patient is unclear. Did the patient have myelitis? Did they fulfill the Wingerchuk criteria for NMO? If the patient did not meet the criteria, the diagnosis should be NMO spectrum disorder.

2. During the 12 years of disease duration, how many relapses did the patient
experience?

3. After the initial episode, how long was low-dose prednisolone administered to the patient?

4. At the time of development of visual disturbance in the right eye, did the patient receive any corticosteroids?

5. The authors should describe the patient’s color vision. Was this also impaired?
