Reviewer’s report

Title: Acute spontaneous neck haematoma in infants: a rare entity

Version: 3 Date: 13 December 2014

Reviewer: Ramesh S Bhandari

Reviewer’s report:

Major:
19 month and 30 month age is not infant.
Children presented in 7 days or 10 days of illness?
1st case presentations are more in favour of abscess rather than haematoma like fever, inflammatory response increased in laboratory findings so mention some strong radiological features to support haematoma.
mention the rational of doing CT scan in this age group where MRI is available.
Minor: mention clearly regarding hematoma punture, fine needle aspiration because these procedures may be therapeutic in small collection of pus or blood.
Discretionary: add some recent article reference in discussion regarding spontaneous neck haematoma

Level of interest: An article of importance in its field

Quality of written English: Needs some language corrections before being published

Statistical review: No, the manuscript does not need to be seen by a statistician.
